1 Arithmetic and Boolean Expressions

theory *AExp* **imports** *Main* **begin**

1.1 Arithmetic Expressions

type_synonym *vname* = *string*
type_synonym *val* = *int*
type_synonym *state* = *vname* ⇒ *val*

datatype *aexp* = *N int* | *V vname* | *Plus aexp aexp*

fun *aval* :: *aexp* ⇒ *state* ⇒ *val* **where**
aval (*N n*) *s* = *n* |
aval (*V x*) *s* = *s x* |
aval (*Plus* a_1 a_2) *s* = *aval* a_1 *s* + *aval* a_2 *s*

value *aval* (*Plus* (*V* ''*x*'') (*N 5*)) (λ*x*. *if x* = ''*x*'' *then 7 else 0*)

The same state more concisely:

value *aval* (*Plus* (*V* ''*x*'') (*N 5*)) ((λ*x*. *0*) (''*x*'':= *7*))

A little syntax magic to write larger states compactly:

definition *null_state* (<>) **where**
null_state ≡ λ*x*. *0*
syntax
*State* :: *updbinds* => 'a (<>)
translations
_*State ms* == _*Update* <> *ms*
_*State* (_*updbinds b bs*) <= _*Update* (_*State b*) *bs*

We can now write a series of updates to the function λ*x*. *0* compactly:

lemma <*a* := *1*, *b* := *2*> = (<> (*a* := *1*)) (*b* := (*2*::*int*))
by (*rule refl*)

value *aval* (*Plus* (*V* ''*x*'') (*N 5*)) <''*x*'' := *7*>

In the <*a* := *b*> syntax, variables that are not mentioned are 0 by default:

value *aval* (*Plus* (*V* ''*x*'') (*N 5*)) <''*y*'' := *7*>

Note that this <...> syntax works for any function space $\tau_1 \Rightarrow \tau_2$ where τ_2 has a *0*.

1.2 Constant Folding

Evaluate constant subsexpressions:

fun *asimp_const* :: *aexp* ⇒ *aexp* **where**
asimp_const (*N n*) = *N n* |
asimp_const (*V x*) = *V x* |
asimp_const (*Plus* a_1 a_2) =
  (*case* (*asimp_const* a_1, *asimp_const* a_2) *of*
    (*N* n_1, *N* n_2) ⇒ *N*(n_1+n_2) |
    (b_1,b_2) ⇒ *Plus* b_1 b_2)

theorem *aval_asimp_const*:
  aval (*asimp_const a*) *s* = *aval a s*
apply(*induction a*)
apply (*auto split*: *aexp.split*)
done

Now we also eliminate all occurrences 0 in additions. The standard method: optimized versions of the constructors:

fun *plus* :: *aexp* ⇒ *aexp* ⇒ *aexp* **where**
plus (*N* i_1) (*N* i_2) = *N*(i_1+i_2) |
plus (*N i*) *a* = (*if i=0 then a else Plus* (*N i*) *a*) |
plus a (*N i*) = (*if i=0 then a else Plus a* (*N i*)) |
plus a_1 a_2 = *Plus* a_1 a_2

lemma *aval_plus*[*simp*]:
  aval (*plus a1 a2*) *s* = *aval a1 s* + *aval a2 s*
apply(*induction a1 a2 rule*: *plus.induct*)
apply *simp_all*
done

fun *asimp* :: *aexp* ⇒ *aexp* **where**
asimp (*N n*) = *N n* |
asimp (*V x*) = *V x* |
asimp (*Plus* a_1 a_2) = *plus* (*asimp* a_1) (*asimp* a_2)

Note that in *asimp_const* the optimized constructor was inlined. Making it a separate function *AExp.plus* improves modularity of the code and the proofs.

value *asimp* (*Plus* (*Plus* (*N 0*) (*N 0*)) (*Plus* (*V* ″*x*″) (*N 0*)))

theorem *aval_asimp*[*simp*]:
  aval (*asimp a*) *s* = *aval a s*
apply(*induction a*)

apply *simp_all*
done

end
theory *BExp* **imports** *AExp* **begin**

1.3 Boolean Expressions

datatype *bexp* = *Bc bool* | *Not bexp* | *And bexp bexp* | *Less aexp aexp*
fun *bval* :: *bexp* ⇒ *state* ⇒ *bool* **where**
bval (*Bc v*) *s* = *v* |
bval (*Not b*) *s* = (¬ *bval b s*) |
bval (*And* b_1 b_2) *s* = (*bval* b_1 *s* ∧ *bval* b_2 *s*) |
bval (*Less* a_1 a_2) *s* = (*aval* a_1 *s* < *aval* a_2 *s*)

value *bval* (*Less* (*V* ″*x*″) (*Plus* (*N 3*) (*V* ″*y*″)))
<″*x*″ := *3*, ″*y*″ := *1*>

1.4 Constant Folding

Optimizing constructors:

fun *less* :: *aexp* ⇒ *aexp* ⇒ *bexp* **where**
less (*N* n_1) (*N* n_2) = *Bc*(n_1 < n_2) |
less a_1 a_2 = *Less* a_1 a_2

lemma [*simp*]: *bval* (*less a1 a2*) *s* = (*aval a1 s* < *aval a2 s*)
apply(*induction a1 a2 rule*: *less.induct*)
apply *simp_all*
done

fun *and* :: *bexp* ⇒ *bexp* ⇒ *bexp* **where**
and (*Bc True*) *b* = *b* |
and b (*Bc True*) = *b* |
and (*Bc False*) *b* = *Bc False* |
and b (*Bc False*) = *Bc False* |
and b_1 b_2 = *And* b_1 b_2

lemma *bval_and*[*simp*]: *bval* (*and b1 b2*) *s* = (*bval b1 s* ∧ *bval b2 s*)
apply(*induction b1 b2 rule*: *and.induct*)
apply *simp_all*
done

fun *not* :: *bexp* ⇒ *bexp* **where**
not (*Bc True*) = *Bc False* |

not (Bc False) = Bc True |
not b = Not b

lemma *bval_not*[*simp*]: *bval (not b) s = (¬ bval b s)*
apply(*induction b rule*: *not.induct*)
apply *simp_all*
done

Now the overall optimizer:

fun *bsimp* :: *bexp* ⇒ *bexp* **where**
bsimp (Bc v) = Bc v |
bsimp (Not b) = not(*bsimp b*) *|*
bsimp (And b_1 b_2*) = and (bsimp* b_1*) (bsimp* b_2*) |*
bsimp (Less a_1 a_2*) = less (asimp* a_1*) (asimp* a_2*)*

value *bsimp (And (Less (N 0) (N 1)) b)*

value *bsimp (And (Less (N 1) (N 0)) (Bc True))*

theorem *bval (bsimp b) s = bval b s*
apply(*induction b*)
apply *simp_all*
done

end

3.1 Big-Step Semantics of Commands

The big-step semantics is a straight-forward inductive definition with concrete syntax. Note that the first parameter is a tuple, so the syntax becomes $(c,s) \Rightarrow s'$.

inductive
big_step :: *com* × *state* ⇒ *state* ⇒ *bool* (**infix** ⇒ *55*)
where
Skip: (*SKIP*,*s*) ⇒ *s* |
Assign: (*x* ::= *a*,*s*) ⇒ *s*(*x* := *aval a s*) |
Seq: ⟦ (*c*$_1$,*s*$_1$) ⇒ *s*$_2$; (*c*$_2$,*s*$_2$) ⇒ *s*$_3$ ⟧ ⟹ (*c*$_1$;;*c*$_2$, *s*$_1$) ⇒ *s*$_3$ |

IfTrue: ⟦ *bval b s*; (*c*$_1$,*s*) ⇒ *t* ⟧ ⟹ (*IF b THEN c*$_1$ *ELSE c*$_2$, *s*) ⇒ *t* |
IfFalse: ⟦ ¬*bval b s*; (*c*$_2$,*s*) ⇒ *t* ⟧ ⟹ (*IF b THEN c*$_1$ *ELSE c*$_2$, *s*) ⇒ *t* |
WhileFalse: ¬*bval b s* ⟹ (*WHILE b DO c*,*s*) ⇒ *s* |
WhileTrue:
⟦ *bval b s*$_1$; (*c*,*s*$_1$) ⇒ *s*$_2$; (*WHILE b DO c*, *s*$_2$) ⇒ *s*$_3$ ⟧
⟹ (*WHILE b DO c*, *s*$_1$) ⇒ *s*$_3$

schematic_goal *ex*: (*''x'' ::= N 5;; ''y'' ::= V ''x''*, *s*) ⇒ *?t*
apply(*rule Seq*)
apply(*rule Assign*)
apply *simp*
apply(*rule Assign*)
done

thm *ex*[*simplified*]

We want to execute the big-step rules:

code_pred *big_step* **.**

For inductive definitions we need command `values` instead of `value`.

values {*t*. (*SKIP*, λ_. *0*) ⇒ *t*}

We need to translate the result state into a list to display it.

values {*map t* [*''x''*] |*t*. (*SKIP*, <*''x'' := 42*>) ⇒ *t*}

values {*map t* [*''x''*] |*t*. (*''x'' ::= N 2*, <*''x'' := 42*>) ⇒ *t*}

values {*map t* [*''x''*,*''y''*] |*t*.
(*WHILE Less* (*V ''x''*) (*V ''y''*) *DO* (*''x'' ::= Plus* (*V ''x''*) (*N 5*)),
<*''x'' := 0*, *''y'' := 13*>) ⇒ *t*}

Proof automation:

The introduction rules are good for automatically construction small program executions. The recursive cases may require backtracking, so we declare the set as unsafe intro rules.

declare *big_step.intros* [*intro*]

The standard induction rule

⟦*x1* ⇒ *x2*; ⋀*s*. *P* (*SKIP*, *s*) *s*; ⋀*x a s*. *P* (*x ::= a*, *s*) (*s*(*x := aval a s*));
⋀*c*$_1$ *s*$_1$ *s*$_2$ *c*$_2$ *s*$_3$.
⟦(*c*$_1$, *s*$_1$) ⇒ *s*$_2$; *P* (*c*$_1$, *s*$_1$) *s*$_2$; (*c*$_2$, *s*$_2$) ⇒ *s*$_3$; *P* (*c*$_2$, *s*$_2$) *s*$_3$⟧
⟹ *P* (*c*$_1$;; *c*$_2$, *s*$_1$) *s*$_3$;
⋀*b s c*$_1$ *t c*$_2$.

$[\![bval\ b\ s;\ (c_1,\ s) \Rightarrow t;\ P\ (c_1,\ s)\ t]\!] \Longrightarrow P\ (IF\ b\ THEN\ c_1\ ELSE\ c_2,\ s)\ t;$
$\bigwedge b\ s\ c_2\ t\ c_1.$
$[\![\neg\ bval\ b\ s;\ (c_2,\ s) \Rightarrow t;\ P\ (c_2,\ s)\ t]\!] \Longrightarrow P\ (IF\ b\ THEN\ c_1\ ELSE\ c_2,\ s)\ t;$
$\bigwedge b\ s\ c.\ \neg\ bval\ b\ s \Longrightarrow P\ (WHILE\ b\ DO\ c,\ s)\ s;$
$\bigwedge b\ s_1\ c\ s_2\ s_3.$
$[\![bval\ b\ s_1;\ (c,\ s_1) \Rightarrow s_2;\ P\ (c,\ s_1)\ s_2;\ (WHILE\ b\ DO\ c,\ s_2) \Rightarrow s_3;$
$P\ (WHILE\ b\ DO\ c,\ s_2)\ s_3]\!]$
$\Longrightarrow P\ (WHILE\ b\ DO\ c,\ s_1)\ s_3]\!]$
$\Longrightarrow P\ x1\ x2$

thm *big_step.induct*

This induction schema is almost perfect for our purposes, but our trick for reusing the tuple syntax means that the induction schema has two parameters instead of the c, s, and s' that we are likely to encounter. Splitting the tuple parameter fixes this:

lemmas *big_step_induct* = *big_step.induct*[*split_format*(*complete*)]
thm *big_step_induct*

$[\![(x1a,\ x1b) \Rightarrow x2a;\ \bigwedge s.\ P\ SKIP\ s\ s;\ \bigwedge x\ a\ s.\ P\ (x ::= a)\ s\ (s(x := aval\ a\ s));$
$\bigwedge c_1\ s_1\ s_2\ c_2\ s_3.$
$[\![(c_1,\ s_1) \Rightarrow s_2;\ P\ c_1\ s_1\ s_2;\ (c_2,\ s_2) \Rightarrow s_3;\ P\ c_2\ s_2\ s_3]\!]$
$\Longrightarrow P\ (c_1;;\ c_2)\ s_1\ s_3;$
$\bigwedge b\ s\ c_1\ t\ c_2.$
$[\![bval\ b\ s;\ (c_1,\ s) \Rightarrow t;\ P\ c_1\ s\ t]\!] \Longrightarrow P\ (IF\ b\ THEN\ c_1\ ELSE\ c_2)\ s\ t;$
$\bigwedge b\ s\ c_2\ t\ c_1.$
$[\![\neg\ bval\ b\ s;\ (c_2,\ s) \Rightarrow t;\ P\ c_2\ s\ t]\!] \Longrightarrow P\ (IF\ b\ THEN\ c_1\ ELSE\ c_2)\ s\ t;$
$\bigwedge b\ s\ c.\ \neg\ bval\ b\ s \Longrightarrow P\ (WHILE\ b\ DO\ c)\ s\ s;$
$\bigwedge b\ s_1\ c\ s_2\ s_3.$
$[\![bval\ b\ s_1;\ (c,\ s_1) \Rightarrow s_2;\ P\ c\ s_1\ s_2;\ (WHILE\ b\ DO\ c,\ s_2) \Rightarrow s_3;$
$P\ (WHILE\ b\ DO\ c)\ s_2\ s_3]\!]$
$\Longrightarrow P\ (WHILE\ b\ DO\ c)\ s_1\ s_3]\!]$
$\Longrightarrow P\ x1a\ x1b\ x2a$

3.2 Rule inversion

What can we deduce from $(SKIP,\ s) \Rightarrow t$? That $s = t$. This is how we can automatically prove it:

inductive_cases *SkipE*[*elim*!]: $(SKIP,s) \Rightarrow t$

thm *SkipE*

This is an *elimination rule*. The [elim] attribute tells auto, blast and friends (but not simp!) to use it automatically; [elim!] means that it is applied eagerly.

Similarly for the other commands:

inductive_cases *AssignE*[*elim*!]: $(x ::= a,s) \Rightarrow t$
thm *AssignE*
inductive_cases *SeqE*[*elim*!]: $(c1;;c2,s1) \Rightarrow s3$
thm *SeqE*
inductive_cases *IfE*[*elim*!]: $(IF\ b\ THEN\ c1\ ELSE\ c2,s) \Rightarrow t$
thm *IfE*

inductive_cases *WhileE*[*elim*]: $(WHILE\ b\ DO\ c,s) \Rightarrow t$
thm *WhileE*

Only [elim]: [elim!] would not terminate.

An automatic example:

lemma $(IF\ b\ THEN\ SKIP\ ELSE\ SKIP,\ s) \Rightarrow t \Longrightarrow t = s$
by *blast*

Rule inversion by hand via the "cases" method:

lemma assumes $(IF\ b\ THEN\ SKIP\ ELSE\ SKIP,\ s) \Rightarrow t$

3.3 Command Equivalence

We call two statements c and c' equivalent wrt. the big-step semantics when *c started in s terminates in s′ iff c′ started in the same s also terminates in the same s′*. Formally:

abbreviation
equiv_c :: *com* ⇒ *com* ⇒ *bool* (**infix** ∼ *50*) **where**
c ∼ *c′* ≡ (∀ *s t*. (*c*,*s*) ⇒ *t* = (*c′*,*s*) ⇒ *t*)

Warning: ∼ is the symbol written `\ < s i m >` (without spaces).

As an example, we show that loop unfolding is an equivalence transformation on programs:

lemma *unfold_while*:
(*WHILE b DO c*) ∼ (*IF b THEN c*;; *WHILE b DO c ELSE SKIP*) (**is** *?w* ∼ *?iw*)
proof −
— to show the equivalence, we look at the derivation tree for
— each side and from that construct a derivation tree for the other side
{ fix *s t* **assume** (*?w*, *s*) ⇒ *t*
— as a first thing we note that, if *b* is *False* in state *s*,
— then both statements do nothing:
{ assume ¬*bval b s*
hence *t* = *s* **using** ‹(*?w*,*s*) ⇒ *t*› **by** *blast*
hence (*?iw*, *s*) ⇒ *t* **using** ‹¬*bval b s*› **by** *blast*
}
moreover
— on the other hand, if *b* is *True* in state *s*,
— then only the *WhileTrue* rule can have been used to derive (*?w*, *s*) ⇒ *t*

```
  { assume bval b s
    with ⟨(?w, s) ⇒ t⟩ obtain s' where
      (c, s) ⇒ s' and (?w, s') ⇒ t by auto
    — now we can build a derivation tree for the IF
    — first, the body of the True-branch:
    hence (c;; ?w, s) ⇒ t by (rule Seq)
    — then the whole IF
    with ⟨bval b s⟩ have (?iw, s) ⇒ t by (rule IfTrue)
  }
  ultimately
  — both cases together give us what we want:
  have (?iw, s) ⇒ t by blast
}
moreover
— now the other direction:
{ fix s t assume (?iw, s) ⇒ t
  — again, if b is False in state s, then the False-branch
  — of the IF is executed, and both statements do nothing:
  { assume ¬bval b s
    hence s = t using ⟨(?iw, s) ⇒ t⟩ by blast
    hence (?w, s) ⇒ t using ⟨¬bval b s⟩ by blast
  }
  moreover
  — on the other hand, if b is True in state s,
  — then this time only the IfTrue rule can have be used
  { assume bval b s
    with ⟨(?iw, s) ⇒ t⟩ have (c;; ?w, s) ⇒ t by auto
    — and for this, only the Seq-rule is applicable:
    then obtain s' where
      (c, s) ⇒ s' and (?w, s') ⇒ t by auto
   — with this information, we can build a derivation tree for the WHILE

    with ⟨bval b s⟩
    have (?w, s) ⇒ t by (rule WhileTrue)
  }
  ultimately
  — both cases together again give us what we want:
  have (?w, s) ⇒ t by blast
}
ultimately
show ?thesis by blast

4.3 Proof infrastructure

4.3.1 Induction rules

The default induction rule *small_step.induct* only works for lemmas of the form $a \to b \Longrightarrow \ldots$ where a and b are not already pairs (*DUMMY*,*DUMMY*). We can generate a suitable variant of *small_step.induct* for pairs by "splitting" the arguments → into pairs:

lemmas *small_step_induct* = *small_step.induct*[*split_format*(*complete*)]

4.3.2 Proof automation

declare *small_step.intros*[*simp*,*intro*]

Rule inversion:

inductive_cases *IfE*[*elim*!]: (*IF b THEN c1 ELSE c2*,*s*) → *ct*
inductive_cases *WhileE*[*elim*]: (*WHILE b DO c*, *s*) → *ct*

A simple property:

Each case of the induction can be proved automatically:

```

lemma small_to_big:
  cs →* (SKIP,t) ⟹ cs ⇒ t
apply (induction cs (SKIP,t) rule: star.induct)
apply (auto intro: small1_big_continue)
done
```

Finally, the equivalence theorem:

theorem *big_iff_small*:
$cs \Rightarrow t = cs \rightarrow* (SKIP,t)$
by(*metis big_to_small small_to_big*)

4.5 Final configurations and infinite reductions

definition *final* $cs \longleftrightarrow \neg(EX\ cs'.\ cs \rightarrow cs')$

lemma *finalD*: *final* $(c,s) \Longrightarrow c = SKIP$
apply(*simp add*: *final_def*)
apply(*induction c*)
apply *blast+*
done

lemma *final_iff_SKIP*: *final* $(c,s) = (c = SKIP)$
by (*metis SkipE finalD final_def*)

Now we can show that $\Rightarrow$ yields a final state iff $\rightarrow$ terminates:

lemma *big_iff_small_termination*:
$(EX\ t.\ cs \Rightarrow t) \longleftrightarrow (EX\ cs'.\ cs \rightarrow* cs' \wedge final\ cs')$
by(*simp add*: *big_iff_small final_iff_SKIP*)

This is the same as saying that the absence of a big step result is equivalent with absence of a terminating small step sequence, i.e. with nontermination. Since $\rightarrow$ is determininistic, there is no difference between may and must terminate.

5.1 List setup

In the following, we use the length of lists as integers instead of natural numbers. Instead of converting *nat* to *int* explicitly, we tell Isabelle to coerce *nat* automatically when necessary.

declare [[*coercion_enabled*]]
declare [[*coercion int* :: *nat* $\Rightarrow$ *int*]]

Similarly, we will want to access the ith element of a list, where i is an *int*.

fun *inth* :: $'a$ *list* $\Rightarrow$ *int* $\Rightarrow$ $'a$ (**infixl** !! *100*) **where**

$(x \# xs) !! i = (\mathit{if}\ i = 0\ \mathit{then}\ x\ \mathit{else}\ xs !! (i - 1))$

The only additional lemma we need about this function is indexing over append:

lemma *inth_append* [*simp*]:
$0 \leq i \Longrightarrow$
$(xs @ ys) !! i = (\mathit{if}\ i < \mathit{size}\ xs\ \mathit{then}\ xs !! i\ \mathit{else}\ ys !! (i - \mathit{size}\ xs))$
by (*induction xs arbitrary*: *i*) (*auto simp*: *algebra_simps*)

We hide coercion *int* applied to *length*:

5.3 Verification infrastructure

Below we need to argue about the execution of code that is embedded in larger programs. For this purpose we show that execution is preserved by appending code to the left or right of a program.

lemma *iexec_shift* [*simp*]:
((*n*+*i'*,*s'*,*stk'*) = *iexec x* (*n*+*i*,*s*,*stk*)) = ((*i'*,*s'*,*stk'*) = *iexec x* (*i*,*s*,*stk*))
by(*auto split*:*instr.split*)

lemma *exec1_appendR*: $P \vdash c \to c' \Longrightarrow P@P' \vdash c \to c'$
by (*auto simp*: *exec1_def*)

lemma *exec_appendR*: $P \vdash c \to* c' \Longrightarrow P@P' \vdash c \to* c'$
by (*induction rule*: *star.induct*) (*fastforce intro*: *star.step exec1_appendR*)+

lemma *exec1_appendL*:
fixes *i i'* :: *int*
shows
$P \vdash (i,s,stk) \to (i',s',stk') \Longrightarrow$
$P' @ P \vdash (size(P')+i,s,stk) \to (size(P')+i',s',stk')$
unfolding *exec1_def*
by (*auto simp del*: *iexec.simps*)

lemma *exec_appendL*:
fixes *i i'* :: *int*
shows

$P \vdash (i,s,stk) \rightarrow* (i',s',stk') \implies$
$P' @ P \vdash (size(P')+i,s,stk) \rightarrow* (size(P')+i',s',stk')$
by (*induction rule*: *exec_induct*) (*blast intro*: *star.step exec1_appendL*)+

Now we specialise the above lemmas to enable automatic proofs of $P \vdash c \rightarrow* c'$ where P is a mixture of concrete instructions and pieces of code that we already know how they execute (by induction), combined by @ and #. Backward jumps are not supported. The details should be skipped on a first reading.

If we have just executed the first instruction of the program, drop it:

lemma *exec_Cons_1* [*intro*]:
$P \vdash (0,s,stk) \rightarrow* (j,t,stk') \implies$
$instr\#P \vdash (1,s,stk) \rightarrow* (1+j,t,stk')$
by (*drule exec_appendL*[**where** P'=[*instr*]]) *simp*

lemma *exec_appendL_if*[*intro*]:
fixes $i\ i'\ j$ :: *int*
shows
$size\ P' <= i$
$\implies P \vdash (i - size\ P',s,stk) \rightarrow* (j,s',stk')$
$\implies i' = size\ P' + j$
$\implies P' @ P \vdash (i,s,stk) \rightarrow* (i',s',stk')$
by (*drule exec_appendL*[**where** P'=P']) *simp*

Split the execution of a compound program up into the execution of its parts:

lemma *exec_append_trans*[*intro*]:
fixes $i'\ i''\ j''$ :: *int*
shows
$P \vdash (0,s,stk) \rightarrow* (i',s',stk') \implies$
$size\ P \leq i' \implies$
$P' \vdash\ (i' - size\ P,s',stk') \rightarrow* (i'',s'',stk'') \implies$
$j'' = size\ P + i''$
$\implies$
$P\ @\ P' \vdash (0,s,stk) \rightarrow* (j'',s'',stk'')$

Warning: the ":" notation leads to syntactic ambiguities, i.e. multiple parse trees, because ":" also stands for set membership. In most situations Isabelle's type system will reject all but one parse tree, but will still inform you of the potential ambiguity.

8.3 The Standard Typing System

The predicate $l \vdash c$ is nicely intuitive and executable. The standard formulation, however, is slightly different, replacing the maximum computation by an antimonotonicity rule. We introduce the standard system now and show the equivalence with our formulation.

8.6 The Standard Termination-Sensitive System

The predicate $l \vdash c$ is nicely intuitive and executable. The standard formulation, however, is slightly different, replacing the maximum computation by an antimonotonicity rule. We introduce the standard system now and show the equivalence with our formulation.

9.1 The Variables in an Expression

We need to collect the variables in both arithmetic and boolean expressions. For a change we do not introduce two functions, e.g. *avars* and *bvars*, but we overload the name *vars* via a *type class*, a device that originated with Haskell:

class *vars* =
fixes *vars* :: $'a \Rightarrow$ *vname set*

This defines a type class "vars" with a single function of (coincidentally) the same name. Then we define two separated instances of the class, one for *aexp* and one for *bexp*:

instantiation *aexp* :: *vars*
begin

fun *vars_aexp* :: *aexp* $\Rightarrow$ *vname set* **where**
vars (*N n*) = {} |
vars (*V x*) = {*x*} |
vars (*Plus* a_1 a_2) = *vars* a_1 $\cup$ *vars* a_2

  DO (*''y''* ::= *Plus* (*V ''y''*) (*V ''x''*);;
    ''x'' ::= *Plus* (*V ''x''*) (*N* (− *1*)))

13.1.1 Proof by Operational Semantics

The behaviour of the loop is proved by induction:

lemma *while_sum*:
  (*wsum*, *s*) ⇒ *t* ⟹ *t ''y''* = *s ''y''* + *sum*(*s ''x''*)
apply(*induction wsum s t rule*: *big_step_induct*)
apply(*auto*)
done

We were lucky that the proof was automatic, except for the induction. In general, such proofs will not be so easy. The automation is partly due to the right inversion rules that we set up as automatic elimination rules that decompose big-step premises.

Now we prefix the loop with the necessary initialization:

lemma *sum_via_bigstep*:
  assumes (*''y''* ::= *N 0*;; *wsum*, *s*) ⇒ *t*
  shows *t ''y''* = *sum* (*s ''x''*)

  from *while_sum*[*OF this*] **show** *?thesis* **by** *simp*
qed

13.1.2 Proof by Hoare Logic

Note that we deal with sequences of commands from right to left, pulling back the postcondition towards the precondition.

lemma ⊢ {λ*s*. *s ''x''* = *n*} *''y''* ::= *N 0*;; *wsum* {λ*s*. *s ''y''* = *sum n*}
apply(*rule Seq*)
 prefer *2*
 apply(*rule While'* [**where** *P* = λ*s*. (*s ''y''* = *sum n* − *sum*(*s ''x''*))])
  apply(*rule Seq*)
   prefer *2*
   apply(*rule Assign*)
  apply(*rule Assign'*)
  apply *simp*

apply *simp*
apply(*rule Assign'*)
apply *simp*
done

The proof is intentionally an apply script because it merely composes the rules of Hoare logic. Of course, in a few places side conditions have to be proved. But since those proofs are 1-liners, a structured proof is overkill. In fact, we shall learn later that the application of the Hoare rules can be automated completely and all that is left for the user is to provide the loop invariants and prove the side-conditions.

13.4 Hoare Logic for Total Correctness

```
theory Hoare_Total
imports Hoare_Examples
```

begin

13.4.1 Hoare Logic for Total Correctness — Separate Termination Relation

Note that this definition of total validity $\models_t$ only works if execution is deterministic (which it is in our case).

definition *hoare_tvalid* :: *assn* ⇒ *com* ⇒ *assn* ⇒ *bool*
(⊨$_t$ {(*1*_)}/ (_)/ {(*1*_)} *50*) **where**
⊨$_t$ {*P*}*c*{*Q*} ⟷ (∀ *s*. *P s* ⟶ (∃ *t*. (*c*,*s*) ⇒ *t* ∧ *Q t*))

Provability of Hoare triples in the proof system for total correctness is written ⊢$_t$ {*P*}*c*{*Q*} and defined inductively. The rules for ⊢$_t$ differ from those for ⊢ only in the one place where nontermination can arise: the *While*-rule.

inductive
hoaret :: *assn* ⇒ *com* ⇒ *assn* ⇒ *bool* (⊢$_t$ ({(*1*_)}/ (_)/ {(*1*_)}) *50*)
where

Skip: ⊢$_t$ {*P*} *SKIP* {*P*} |

Assign: ⊢$_t$ {λ*s*. *P*(*s*[*a*/*x*])} *x*::=*a* {*P*} |

Seq: ⟦ ⊢$_t$ {*P*$_1$} *c*$_1$ {*P*$_2$}; ⊢$_t$ {*P*$_2$} *c*$_2$ {*P*$_3$} ⟧ ⟹ ⊢$_t$ {*P*$_1$} *c*$_1$;;*c*$_2$ {*P*$_3$} |

If: ⟦ ⊢$_t$ {λ*s*. *P s* ∧ *bval b s*} *c*$_1$ {*Q*}; ⊢$_t$ {λ*s*. *P s* ∧ ¬ *bval b s*} *c*$_2$ {*Q*} ⟧
⟹ ⊢$_t$ {*P*} *IF b THEN c*$_1$ *ELSE c*$_2$ {*Q*} |

While:
(⋀*n*::*nat*.
⊢$_t$ {λ*s*. *P s* ∧ *bval b s* ∧ *T s n*} *c* {λ*s*. *P s* ∧ (∃ *n*′<*n*. *T s n*′)})
⟹ ⊢$_t$ {λ*s*. *P s* ∧ (∃ *n*. *T s n*)} *WHILE b DO c* {λ*s*. *P s* ∧ ¬*bval b s*} |

conseq: ⟦ ∀ *s*. *P*′ *s* ⟶ *P s*; ⊢$_t$ {*P*}*c*{*Q*}; ∀ *s*. *Q s* ⟶ *Q*′ *s* ⟧ ⟹
⊢$_t$ {*P*′}*c*{*Q*′}

The *While*-rule is like the one for partial correctness but it requires additionally that with every execution of the loop body some measure relation *T* :: *state* ⇒ *nat* ⇒ *bool* decreases. The following functional version is more intuitive:

lemma *While_fun*:
⟦ ⋀*n*::*nat*. ⊢$_t$ {λ*s*. *P s* ∧ *bval b s* ∧ *n* = *f s*} *c* {λ*s*. *P s* ∧ *f s* < *n*}⟧
⟹ ⊢$_t$ {*P*} *WHILE b DO c* {λ*s*. *P s* ∧ ¬*bval b s*}
by (*rule While* [**where** *T*=λ*s n*. *n* = *f s*, *simplified*])

Building in the consequence rule:

lemma *strengthen_pre*:
$[\![\forall s.\ P'\ s \longrightarrow P\ s;\ \vdash_t \{P\}\ c\ \{Q\}]\!] \Longrightarrow \vdash_t \{P'\}\ c\ \{Q\}$
by (*metis conseq*)

lemma *weaken_post*:
$[\![\vdash_t \{P\}\ c\ \{Q\};\ \forall s.\ Q\ s \longrightarrow Q'\ s]\!] \Longrightarrow \vdash_t \{P\}\ c\ \{Q'\}$
by (*metis conseq*)

lemma *Assign'*: $\forall s.\ P\ s \longrightarrow Q(s[a/x]) \Longrightarrow \vdash_t \{P\}\ x ::= a\ \{Q\}$
by (*simp add*: *strengthen_pre*[*OF* _ *Assign*])

lemma *While_fun'*:
assumes $\bigwedge n{::}nat.\ \vdash_t \{\lambda s.\ P\ s \wedge bval\ b\ s \wedge n = f\ s\}\ c\ \{\lambda s.\ P\ s \wedge f\ s < n\}$
and $\forall s.\ P\ s \wedge \neg\ bval\ b\ s \longrightarrow Q\ s$
shows $\vdash_t \{P\}\ WHILE\ b\ DO\ c\ \{Q\}$
by(*blast intro*: *assms*(*1*) *weaken_post*[*OF While_fun assms*(*2*)])

Our standard example:

lemma $\vdash_t \{\lambda s.\ s\ ''x'' = i\}\ ''y'' ::= N\ 0;;\ wsum\ \{\lambda s.\ s\ ''y'' = sum\ i\}$
apply(*rule Seq*)
prefer *2*
apply(*rule While_fun'* [**where** $P = \lambda s.\ (s\ ''y'' = sum\ i - sum(s\ ''x''))$
and $f = \lambda s.\ nat(s\ ''x'')$])
apply(*rule Seq*)
prefer *2*
apply(*rule Assign*)
apply(*rule Assign'*)
apply *simp*
apply(*simp*)
apply(*rule Assign'*)
apply *simp*
done

The soundness theorem:

theorem *hoaret_sound*: $\vdash_t \{P\}c\{Q\} \implies \models_t \{P\}c\{Q\}$
proof(*unfold hoare_tvalid_def*, *induction rule*: *hoaret.induct*)
case (*While P b T c*)
{
fix *s n*
have $[\![P\ s;\ T\ s\ n]\!] \Longrightarrow \exists t.\ (WHILE\ b\ DO\ c, s) \Rightarrow t \wedge P\ t \wedge \neg\ bval\ b\ t$
proof(*induction n arbitrary*: *s rule*: *less_induct*)
case (*less n*)
thus *?case* **by** (*metis While.IH WhileFalse WhileTrue*)

```
  qed
 }
 thus ?case by auto
next
 case If thus ?case by auto blast
qed fastforce+
```

The completeness proof proceeds along the same lines as the one for partial correctness. First we have to strengthen our notion of weakest precondition to take termination into account:

```
definition wpt :: com ⇒ assn ⇒ assn (wp_t) where
wp_t c Q = (λs. ∃t. (c,s) ⇒ t ∧ Q t)

lemma [simp]: wp_t SKIP Q = Q
by(auto intro!: ext simp: wpt_def)

lemma [simp]: wp_t (x ::= e) Q = (λs. Q(s(x := aval e s)))
by(auto intro!: ext simp: wpt_def)

lemma [simp]: wp_t (c1;;c2) Q = wp_t c1 (wp_t c2 Q)
unfolding wpt_def
apply(rule ext)
apply auto
done

lemma [simp]:
 wp_t (IF b THEN c1 ELSE c2) Q = (λs. wp_t (if bval b s then c1 else c2) Q
s)
apply(unfold wpt_def)
apply(rule ext)
apply auto
done
```

Now we define the number of iterations *WHILE b DO c* needs to terminate when started in state *s*. Because this is a truly partial function, we define it as an (inductive) relation first:

```
inductive Its :: bexp ⇒ com ⇒ state ⇒ nat ⇒ bool where
Its_0: ¬ bval b s ⟹ Its b c s 0 |
Its_Suc: ⟦ bval b s; (c,s) ⇒ s'; Its b c s' n ⟧ ⟹ Its b c s (Suc n)
```

The relation is in fact a function:

```
lemma Its_fun: Its b c s n ⟹ Its b c s n' ⟹ n=n'
proof(induction arbitrary: n' rule:Its.induct)
 case Its_0 thus ?case by(metis Its.cases)
```

next
case *Its_Suc* **thus** *?case* **by**(*metis Its.cases big_step_determ*)
qed

For all terminating loops, *Its* yields a result:

lemma *WHILE_Its*: (*WHILE b DO c*,*s*) ⇒ *t* ⟹ ∃ *n*. *Its b c s n*

14.4 Pretty printing state sets

Tweak code generation to work with sets of non-equality types:

declare *insert_code*[*code del*] *union_coset_filter*[*code del*]
lemma *insert_code* [*code*]: *insert x* (*set xs*) = *set* (*x*#*xs*)
by *simp*

Compensate for the fact that sets may now have duplicates:

definition *compact* :: *'a set* ⇒ *'a set* **where**
compact X = *X*

lemma [*code*]: *compact*(*set xs*) = *set*(*remdups xs*)
by(*simp add*: *compact_def*)

definition *vars_acom* = *compact o vars o strip*

In order to display commands annotated with state sets, states must be translated into a printable format as sets of variable-state pairs, for the variables in the command:

definition *show_acom* :: *state set acom* ⇒ (*vname*∗*val*)*set set acom* **where**
show_acom C =
  annotate (λ*p*. (λ*s*. (λ*x*. (*x*, *s x*)) ‘ (*vars_acom C*)) ‘ *anno C p*) (*strip C*)

  DO ''x'' ::= *Plus* (*V ''x''*) (*N 2*)
definition *C0* :: *state set acom* **where** *C0* = *annotate* (%*p*. {}) *c0*

The test for *bot* in the *V*-case is important: *bot* indicates that a variable has no possible values, i.e. that the current program point is unreachable. But then the abstract state should collapse to *None*. Put differently, we maintain the invariant that in an abstract state of the form *Some s*, all variables are mapped to non-*bot* values. Otherwise the (pointwise) sup of two abstract states, one of which contains *bot* values, may produce too large a result, thus making the analysis less precise.

14.12.1 Tests

value *show_acom_opt* (*AI_ivl test1_ivl*)

Better than *AI_const*:

value *show_acom_opt* (*AI_ivl test3_const*)
value *show_acom_opt* (*AI_ivl test4_const*)

value *show_acom_opt* (*AI_ivl test6_const*)

value *show_acom* (*steps test2_ivl 1*)
value *show_acom* (*steps test2_ivl 2*)
value *show_acom* (*steps test2_ivl 3*)

Fixed point reached in 2 steps. Not so if the start value of x is known:

value *show_acom_opt* (*AI_ivl test3_ivl*)
value *show_acom* (*steps test3_ivl 0*)
value *show_acom* (*steps test3_ivl 1*)

value *show_acom* (*steps test3_ivl 3*)
value *show_acom* (*steps test3_ivl 4*)
value *show_acom* (*steps test3_ivl 5*)

Takes as many iterations as the actual execution. Would diverge if loop did not terminate. Worse still, as the following example shows: even if the actual execution terminates, the analysis may not. The value of y keeps decreasing as the analysis is iterated, no matter how long:

value *show_acom* (*steps test4_ivl 50*)

Relationships between variables are NOT captured:

value *show_acom_opt* (*AI_ivl test5_ivl*)

Again, the analysis would not terminate:

value *show_acom* (*steps test6_ivl 50*)

The assumptions for widening and narrowing differ because during narrowing we have the invariant $y \le x$ (where y is the next iterate), but during widening there is no such invariant, there we only have that not yet $y \le x$. This complicates the termination proof for widening.

14.13.5 Counterexamples

Widening is increasing by assumption, but $x \le f\ x$ is not an invariant of widening. It can already be lost after the first step:

lemma assumes !!*x y*::′*a*::*wn*. *x ≤ y ⟹ f x ≤ f y*
and *x ≤ f x* **and** *¬ f x ≤ x* **shows** *x ∇ f x ≤ f(x ∇ f x)*
nitpick[*card = 3*, *expect = genuine*, *show_consts*, *timeout = 120*]

oops

Widening terminates but may converge more slowly than Kleene iteration. In the following model, Kleene iteration goes from 0 to the least pfp in one step but widening takes 2 steps to reach a strictly larger pfp:

lemma assumes !!*x y*::′*a*::*wn*. *x ≤ y ⟹ f x ≤ f y*
and *x ≤ f x* **and** *¬ f x ≤ x* **and** *f(f x) ≤ f x*
shows *f(x ∇ f x) ≤ x ∇ f x*
nitpick[*card = 4*, *expect = genuine*, *show_consts*, *timeout = 120*]

oops
